Exercise 3: Threat modeling and risk management framework

 ${\rm TDT4237~2025~Group~100}$ Ana Barrera Novas, Andrea Cicinelli, Nicola Katja Gisela Ferger

Abstract

In this paper, we assess a web-based tool used for managing cyber risks, as well as develop a test plan for it. There are several risks involved, but using this report, the system will be able to improve its overall security.

Keywords: Insert important keywords from your report. Eg. security, webapp, risk analysis etc.

1. Introduction

This report presents a security and risk assessment of a web-based tool used for managing cyber risks in air traffic management (ATM) systems. The tool is meant to help users create, manage, and share risk assessments, making it easier to identify threats and define security needs for other ATM solutions.

We follow a structured method based on the course material, starting by identifying important system assets and goals. We then list possible risks, create diagrams showing how the system could be misused, and analyze technical threats. These results are used to suggest security requirements and a test plan to help improve the system's overall security.

2. Part 1: Risk management framework

For the following subsections, use the Risk Management Framework to fill in the tables. There is not need to write substantial text in these subsections, all information should be apparent in the tables. Latex tables are fairly easy to use, but look at Overleaf Learn (click me) for more info if you run into issues.

2.1. Identified Business Assets

| | Business Assets | | | | |
|---|-----------------|--|--|--|--|
| | ID | Description | | | |
| | A1 | Web Application Platform: the front-end and back-end systems that host the risk assessment tool. | | | |
| | A2 | Risk Data Repository: database storing all user-generated assessments. | | | |
| ĺ | A3 | User Credentials and Profiles: authentication records, roles, permissions and personal data | | | |
| | | | | | |

2.2. Identified Business Goals

| | Business Goals | | | | |
|----|--|--|--|--|--|
| ID | Description | | | | |
| G1 | Accurate and Comprehensive Assessments | | | | |
| G2 | High Availability and Performance | | | | |
| G3 | Data Confidentiality and Integrity | | | | |
| | | | | | |

2.3. Risk Scales and Dimensions

| Likelihood | | | |
|------------|----------------------------------|--|--|
| Low | Unlikely to occur within a year | | |
| Medium | May occur several times per year | | |
| High | Likely to occur monthly | | |
| Extreme | Expected to occur weekly | | |
| | | | |

I divided the "Impact Dimensions" table in 2 because it can't contain all the information in one!

| Impact Dimensions | | | | |
|----------------------------|-----------------------------|------------------------------|--|--|
| Dimension | Low | Medium | | |
| Financial less than \$10 k | | \$10 k-100 k | | |
| Operational | Minor delay | Partial service interruption | | |
| Reputational | Limited stakeholder concern | Notice within industry | | |
| Safety | No injury | First-aid only | | |

| Impact Dimensions | | | |
|-------------------------------------|--|----------------------------------|--|
| Dimension High | | Extreme | |
| Financial \$100 k–1 M | | more than \$1 M | |
| Operational Major disruption | | Complete outage | |
| Reputational National news coverage | | Corporate crisis | |
| Safety Lost-time injury | | Permanent disability or fatality | |

I created possible business risks, linking the likelihood level, the impact dimension, and the risk ranking (which is the average of the two levels mentioned before).

These business risks are going to be linked in the following tables to the technical risks

2.4. Identified Business Risks

| | Business Risks | | | | | |
|-----|---------------------------------------|------------|---------|--------------|--|--|
| ID | Description | Likelihood | Impact | Risk ranking | | |
| BR1 | Inaccurate Risk Assessments: | High | High | High | | |
| | users omit key assets | | | | | |
| | or threats. | | | | | |
| BR2 | Data Breach: | Medium | Extreme | High | | |
| | unauthorized access to | | | | | |
| | sensitive risk data or user profiles. | | | | | |
| BR3 | System Downtime: | Medium | High | High | | |
| | outages or performance issues | | | | | |
| | prevent assessment work. | | | | | |
| BR4 | Regulatory Non-compliance: | Low | High | Medium | | |
| | failure to meet data-protection | | | | | |
| | or industry standards. | | | | | |
| BR5 | Safety Incident: | Low | Extreme | High | | |
| | flawed assessment leads to | | | | | |
| | real-world accident or injury. | | | | | |

2.5. Misuse Case Diagram

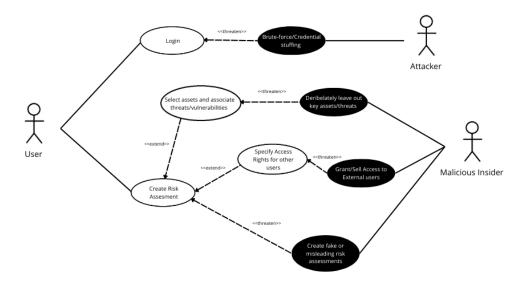

Figure 1: Relevant use cases with their misuse cases

This misuse case diagram shows how the system could be exposed to serious security issues if certain actions are not properly controlled. For example, if someone tries brute-force or credential stuffing attacks, it means the system might not be doing enough to stop repeated login attempts, putting user accounts and sensitive risk data at risk. If a malicious user creates fake or misleading risk assessments, it could lead to wrong decisions being made, especially in critical environments like air traffic management. When someone leaves out important assets or threats on purpose, it affects the quality and reliability of the whole assessment, which could hide real problems so that this could be exploited later. And the possibility of someone sharing access with unauthorized users, or even sells that access, exists, and shows how important it is to have strong rules about who can see or change certain information so that other entities can't exploit it.

2.6. Data Flow Diagram

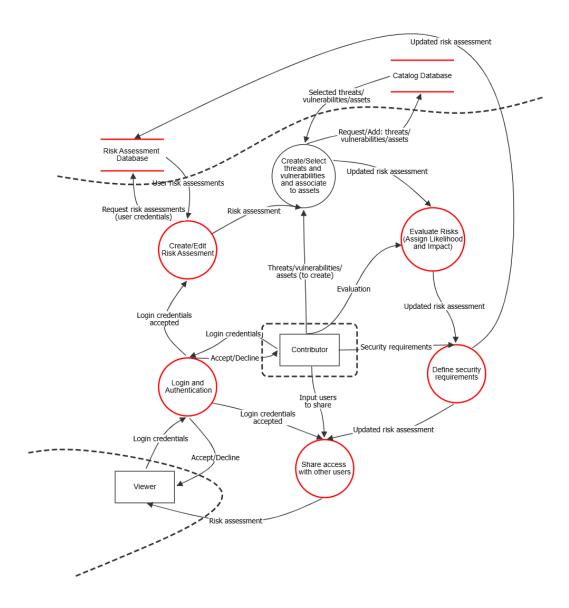

Figure 2: Threat model

The diagram outlines how different types of users interact with the tool and how data flows through its main components. External actors like the Contributor and Viewer are separated from the internal system by a trust boundary, highlighting the shift from untrusted to trusted zones. A second trust boundary surrounds the databases, emphasizing the need to protect stored data from unauthorized access or manipulation. The Contributor is the main user driving most system processes, from logging in and creating assessments to defining risks and sharing access. STRIDE threats are identified at critical points in the flow, showing where vulnerabilities may arise based on user actions, data handling, or lack of proper controls.

The application didn't let us establish correctly the type (STRIDE), as it always put Spoofing and did not let us change it, so we wrote the correct type in the description of the threat in the diagram.

| | Threats | | | | |
|---|----------------------------------|---------------------------|---|--|--|
| Component | Threat title | Type (STRIDE) | Description | | |
| Login and Authentication (process) | Credential Forgery | Spoofing | Attacker tries to log in as another user using stolen or fake credentials | | |
| Login and Authentication (process) | Account Lockout Abuse | Denial of Service | Attacker repeatedly submits bad passwords to trigger lock- out mechanism | | |
| Create/Edit Risk assessment (pro- cess) | No Audit Trail | Repudiation | User actions aren't logged, making it impossible to prove who edited a risk | | |
| Evaluate risks (process) | Risk Value Ma- nipulation | Tampering | Attacker modifies likelihood or impact values to misrepre- sent risk level | | |
| Define security requirements (process) | Leakage of Sensitive Mitigations | Information Disclosure | Requirements are exposed to unauthorized users | | |
| Catalog DB | Inject Fake Threats | Tampering | Malicious user adds invalid or misleading entries | | |
| Risk Assessment DB | Data Exposure | Information Disclosure | Unauthorized party reads sensitive risk assessments | | |
| Share access with other users (process) | Share with untrusted user | Elevation of Privilege | User gives access to someone who should not have it | | |
| Risk Assessment DB | Undetected Data Deletion | Repudiation | A user deletes or modifies a risk assessment entry, but the system lacks proper logging to prove who made the change. | | |
| Share access with other users (process) | Untracked access sharing | Repudiation | A user shares access to a risk assessment with another person, but the system doesn't record who shared it, when, or with whom — making it impossible to track accountability or trace leaks. | | |

2.7. Identified Technical Risks

Using the misuse case diagram, the DFD, and the STRIDE threats, we can now identify the technical risks connected to these misuse cases and threats.

| Technical Risks | | | | |
|-----------------|---|------------|---|-----------------------------|
| ID | Description | Likelihood | Impact | Related Business Risk |
| TR1 | Weak Authentication Mechanism lets attacks brute force credentials. | High | Attackers might get access to other users' accounts | BR1 |
| TR2 | Insufficient Input Validation at Login lets attacks put in SQL code that is then ex- ecuted on the database | Medium | Susceptibility to SQL injections in the login field could lead to security breaches | BR2 |
| TR3 | Attacker types in wrong password several times to lock user accounts | Medium | Users are logged out of their accounts due to account lockout abuse | BR3 |
| TR4 | Susceptibility to DoS Attack - Net- work | Medium | Unexpected downtime e.g. through over- whelming the "Select assets and associate threats" functionality | BR3 |
| TR5 | Session hijacking is used to access contributor's account | Medium | Attacker can modify likelihood, impact and security requirements | BR2 |
| TR6 | No validation on catalog inputs | Low | No server-side validation allows users to insert fake threats or junk data into the threat catalog | BR1 |

| TR7 | Weak database access control, risk assessment db is not properly segmented or pro- tected by strict permissions | Medium | sensitive data exposure. | BR2 |
|------|--|--------|---|-----|
| TR8 | Lack of immutable audit logs; risk modifications aren't recorded with timestamps and user IDs | Medium | undetected tampering or disputes | BR1 |
| TR9 | Access sharing happens without user role validation or periodic review | Medium | Untrusted sharing | BR4 |
| TR10 | Weak access revocation mech- anism; access rights (shared users) cannot be revoked immedi- ately | Low | ex-users could retain unwanted access longer than necessary | BR4 |

2.8. Security requirements

| Security requirements | | | | |
|-----------------------|---|---|--|--|
| Technical | Requirement | Requirement | | |
| risk ID | ID | | | |
| TR1 | SR1 | Two-factor authentication should be required. | | |
| TR1 | SR2 | Logs should contain source and results of login | | |
| 1101 | | attempts. | | |
| TR2 | SR3 All inputs must be validated and sanitized. | | | |
| | | The system must implement account lockout | | |
| TR3 | SR4 | policies with throttling and altering mecha- | | |
| | | nisms. | | |

| TR4 | SR5 | The system must rate-limit requests. |
|-------|-------|---|
| TR5 | SR6 | Session tokens must be transmitted only over |
| 1100 | 5100 | secure channels. |
| TR5 | SR7 | Sessions must have a timeout period. |
| TR6 | SR8 | All inputs to the catalog database must be val- |
| 1100 | 5110 | idated and sanitized. |
| | | Access to the Risk Assessment database must be |
| TR7 | SR9 | restricted based on the principle of least privi- |
| | | lege. |
| | | The system must maintain immutable, tamper- |
| TR8 | SR10 | evident audit logs recording all modifications to |
| 1100 | 51(10 | risk assessments, including timestamps and user |
| | | IDs. |
| | | When users share access, the system must vali- |
| TR9 | SR11 | date the recipient's user role and perform peri- |
| | | odic access reviews. |
| TR9 | SR12 | When users, sahre access the system must and |
| 1109 | 51(12 | perform periodic access reviews. |
| TR10 | SR13 | The system must allow immediate revocation of |
| 11(10 | 51(19 | access rights for any shared user. |

2.9. Test plan

| Test Plan | | | |
|-----------|------------|---------------------|--|
| SR ID | Test ID | Test Priority (1-3) | Test Description |
| SR1 | TC1 | 1 | Verify that after correct username/password entry, the system requires a second factor before granting access. Try logging in without the second factor to confirm it is blocked. |
| SR2 | TC2 | 2 | Attempt several successful and failed logins. Verify that logs capture: username, IP address, timestamp, and login success/failure. Confirm unauthorized access attempts are logged. |
| SR3 | TC3 | 1 | Attempt SQL injection attacks (e.g., OR '1'='1) on login and catalog input fields. Verify that malicious inputs are either sanitized or rejected, and no database errors occur. |
| SR5 | TC4 | 2 | Simulate rapid repeated requests and verify the system enforces rate limiting. |
| SR6 | TC5 | 1 | Monitor traffic using a proxy and confirm that all session tokens are transmitted over HTTPS only (no plaintext transmission). |
| SR7 | TC6 | 2 | Log in as a user and stay idle. Verify that after the configured timeout period (e.g., 15 minutes), the session expires and the user must re-authenticate. |
| S10 | TC7 | 2 | Modify a risk assessment, then check the audit log to ensure it records the action with timestamp, user ID, and prevents any alteration of the record after it is created. |

3. Summary of Findings

We found that the system has several key assets, such as the platform itself, stored risk data, and user information. These need to be protected to avoid problems like data leaks, system downtime, or misleading assessments.

Our analysis identified ten technical risks, including weak login security, missing input checks, and poor access controls. These issues can lead to business problems like incorrect risk reports or even safety incidents.

To reduce these risks, we suggest security measures such as stronger authentication, better logging, and input validation. We also designed a test plan to check that these measures would work if the system were implemented.
